

## CBSE IX Congruence of Triangle Solved Questions

Q. Prove that Sum of Two Sides of a triangle is greater than twice the length of median drawn to third side.

Given:  $\Delta ABC$  in which AD is a median.

To prove:  $AB + AC > 2AD$ .

Construction: Produce AD to E, such that  $AD = DE$ . Join EC.

Proof: In  $\Delta ADB$  and  $\Delta EDC$ ,

$AD = DE$  (Construction)

$BD = CD$  (D is the mid point of BC)

$\angle ADB = \angle EDC$  (Vertically opposite angles)

$\therefore \Delta ADB \cong \Delta EDC$  (SAS congruence criterion)

$\Rightarrow AB = EC$  (CPCT)

In  $\Delta AEC$ ,

$AC + EC > AE$  (Sum of any two sides of a triangles is greater than the third side)

$\therefore AC + AB > 2AD$  ( $AE = AD + DE = AD + AD = 2AD$  &  $EC = AB$ )

Q. ABC is an isosceles triangle in which  $AB = AC$ . Side BA is produced to D such that  $AD = AB$  (see the given figure). Show that  $\angle BCD$  is a right angle.

In  $\Delta ABC$ ,

$AB = AC$  (Given)

$\Rightarrow \angle ACB = \angle ABC$  (Angles opposite to equal sides of a triangle are also equal)

In  $\Delta ACD$ ,  $AC = AD$

$\Rightarrow \angle ADC = \angle ACD$  (Angles opposite to equal sides of a triangle are also equal)

In  $\Delta BCD$ ,

$\angle ABC + \angle BCD + \angle ADC = 180^\circ$  (Angle sum property of a triangle)

$\Rightarrow \angle ACB + \angle ACB + \angle ACD + \angle ACD = 180^\circ$

$\Rightarrow 2(\angle ACB + \angle ACD) = 180^\circ$

$\Rightarrow 2(\angle BCD) = 180^\circ$

$\Rightarrow \angle BCD = 90^\circ$

Q. given: two triangles ABC and PQR in which  $AB=PQ$ ,  $BC=QR$ , median  $AM=$ median  $PN$  prove that triangle ABC is congruent to triangle PQR.

In  $\triangle ABM$  and  $\triangle PQN$

$$AB = PQ \quad (\text{Given})$$

$$AM = PN \quad (\text{Given})$$

And  $BM = QN$  ( As M and N are the midpoint of sides BC and QR respectively and given  $BC= QR$  )

$$\triangle ABM \cong \triangle PQN \quad (\text{By SSS rule})$$

$$\text{SO, } \angle ABM = \angle PQN \quad (\text{by CPCT})$$

Now In  $\triangle ABC$  and  $\triangle PQR$

$$AB = PQ \quad (\text{Given})$$

$$BC = QR \quad (\text{Given})$$

$$\text{And } \angle ABC = \angle PQR \quad (\text{As we proved})$$

$$\triangle ABC \cong \triangle PQR \quad (\text{By SAS rule})$$

( Hence proved )

Q. The vertex angle of an isosceles triangle is twice the sum of its base angles. Find the measure of all the angles.

Let ABC be an isosceles  $\triangle$ . Let the measure of each of the base angles =  $x$

$$\text{Let } \angle B = \angle C = x$$

$$\text{Now, vertex angle} = \angle A = 2x$$

$$\text{Now, } \angle A + \angle B + \angle C = 180^\circ \quad [\text{angle sum property}]$$

$$\Rightarrow 2x + x + x = 180^\circ \Rightarrow 4x = 180 \Rightarrow x = 180/4 = 45^\circ$$

$$\text{So, measure of each of the base angles} = 45^\circ$$

$$\text{Now, measure of the vertex angle} = 90^\circ$$

Q. Prove that the triangle formed by joining the midpoints of the sides of an equilateral triangle is also equilateral.

Let DEF be the midpoints of sides of a triangle ABC ( with D on BC, E on AB and F on AC ).

Now, considering triangles AEF and ABC, angles

$$\angle EAF = \angle BAC \text{ and } AE / AB = 1/2 \text{ and } AF/AC = 1/2.$$

Hence, both triangles are similar by the SAS ( Side - Angle - Side ) criterion and correspondingly as  $AE/AB=AF/AC=EF/BC$  ( similar triangle properties ),  $EF = BC/2$ .

The cases  $DF=AC/2$  and  $DE=AB/2$  can be proved in the same way.

So,  $AB=BC=AC$  (from the given data)

$$2DF=2EF=2DE$$

$$DE=EF=DF$$

So triangle DEF is also Equilateral Triangle

The triangle formed by joining the mid-points of the equilateral triangle is also an equilateral triangle

Q. In triangle PQR,  $PQ > PR$ . QS and RS are the bisectors of angle Q and angle R. Prove that  $SQ > SR$

In  $\triangle PQR$ , we have,

$$PQ > PR \quad [\text{given}]$$

$$\Rightarrow \angle PRQ > \angle PQR \quad [\text{angle opposite to longer side of a } \triangle \text{ is greater}]$$

$$\Rightarrow 12\angle PRQ > 12\angle PQR \quad \dots\dots(1)$$

$$\text{Since, SR bisects } \angle R, \text{ then } \angle SRQ = 1/2\angle PRQ \quad \dots\dots(2)$$

$$\text{Since SQ bisects } \angle P, \text{ then } \angle SQR = 1/2\angle PQR \quad \dots\dots(3)$$

$$\text{Now, from (1), we have } 1/2\angle PRQ > 1/2\angle PQR$$

$$\Rightarrow \angle SRQ > \angle SQR \quad [\text{using (2) and (3)}]$$

$$\text{Now, in } \triangle SQR, \text{ we have } \angle SRQ > \angle SQR \quad [\text{proved above}]$$

$$\Rightarrow SQ > SR \quad [\text{side opposite to greater angle of a } \triangle \text{ is longer}]$$

Q. In triangle ABC (A at the top) , D is any point on the side BC. Prove that  $AB+BC+CA > 2AD$

In triangle ABD,

$$AB+BD > AD \quad (\text{Sum of two sides of a triangle is greater than the third side}) \dots (1)$$

In triangle ACD,

$AC + CD > AD$  (Sum of two sides of a triangle is greater than the third side) ... (2)

Adding eq. (1) and (2)

$$AB + (BD + CD) + AC > AD + AD$$

$$AB + BC + AC > 2AD$$

Q. In triangle ABC, if AB is the greatest side, then prove that angle C is greater than 60 degrees

It is given that, AB is the longest side of the  $\triangle ABC$ .

$AB > BC$  and  $AB > AC$ . Now,  $AB > BC \Rightarrow \angle C > \angle A$  (angle opposite to longer side is greater) ... (1)

Also,  $AB > AC \Rightarrow \angle C > \angle B$  (angle opposite to longer side is greater) ... (2)

adding (1) and (2),

$$\text{we get } \angle C + \angle C > \angle A + \angle B$$

$$\Rightarrow 2\angle C > \angle A + \angle B \Rightarrow 2\angle C + \angle C > \angle A + \angle B + \angle C \Rightarrow 3\angle C > 180^\circ \Rightarrow \angle C > 60^\circ$$

Q. AB and CD are respectively the smallest and longest sides of a quadrilateral ABCD (see the given figure). Show that  $\angle A > \angle C$  and  $\angle B > \angle D$ .

Let us join AC.

In  $\triangle ABC$ ,

$AB < BC$  (AB is the smallest side of quadrilateral ABCD)

$\therefore \angle 2 < \angle 1$  (Angle opposite to the smaller side is smaller) ... (1)

In  $\triangle ADC$ ,

$AD < CD$  (CD is the largest side of quadrilateral ABCD)

$\therefore \angle 4 < \angle 3$  (Angle opposite to the smaller side is smaller) ... (2)

On adding equations (1) and (2), we obtain

$$\angle 2 + \angle 4 < \angle 1 + \angle 3$$

$$\Rightarrow \angle C < \angle A$$

$$\Rightarrow \angle A > \angle C$$

Let us join BD.

In  $\triangle ABD$ ,

$AB < AD$  (AB is the smallest side of quadrilateral ABCD)

$\therefore \angle 8 < \angle 5$  (Angle opposite to the smaller side is smaller) ... (3)

In  $\triangle BDC$ ,

$BC < CD$  (CD is the largest side of quadrilateral ABCD)

$\therefore \angle 7 < \angle 6$  (Angle opposite to the smaller side is smaller) ... (4)

On adding equations (3) and (4), we obtain

$$\angle 8 + \angle 7 < \angle 5 + \angle 6$$

$$\Rightarrow \angle D < \angle B \quad \Rightarrow \angle B > \angle D$$

Q. If S. is any point on the side QR of triangle PQR, prove that  $PQ+QR+RP > 2PS$

In  $\triangle PQS$ ,

$PQ + QS > PS$  (i) .....(Sum of two sides of a triangle is greater than the third side)

In  $\triangle PSR$ ,

$PR + SR > PS$  .....(ii)... Sum of two sides of a triangle is greater than the third side)

Adding (i) and (ii), we get

$$PQ + QS + PR + SR > 2PS$$

$PQ + QR + PR > 2PS$  ( $QS + SR = QR$ ) Hence proved.

Q. Prove that the difference of any two sides of a triangle is less than the third side.

Construction: Take a Point D on AB such that  $AD = AC$  and join CD

Prove that :  $AB - AC < BC$  ,  $AB - BC < AC$  and  $BC-AC < AB$

Proof: In  $\triangle ACD$ , Ext  $\angle 4 > \angle 2$

but ,  $AD = AC \Rightarrow \angle 1 = \angle 2$

So,  $\angle 4 > \angle 1$  -----(i)

Now, In  $\triangle BCD$ , ext  $\angle 1 > \angle 3$  -----(ii)

Then from (i) and (ii)

$$\angle 4 > \angle 3 \Rightarrow BC > BD$$

But,  $BD = AB - AD$  and  $AD = AC \Rightarrow BD = AB - AC$

So,  $BC > AB - AC$

**Q. Prove that Sum of any two sides of triangle is greater than third side .**

**Solution:.**

Construction: Extend BA to D Such that  $AD = AC$

Proof : In  $\triangle ACD$ ,  $DA = CA$ .

Therefore,  $\angle ADC = \angle ACD$  [ isosceles triangle have two equal angles]

$$\angle ADC + \angle 1 > \angle ACD$$

Thus,  $\angle BCD > \angle BDC$  [by Euclid's fifth common notion.]

In  $\triangle DCB$

$$\angle BCD > \angle BDC, \text{ So, } BD > BC.$$

But  $BD = BA + AD$ , and  $AD = AC$ .

Thus,  $BA + AC > BC$ .

A similar argument shows that  $AC + BC > BA$  and  $BA + BC > AC$ .

**OR, Another way to prove**

Draw a triangle,  $\triangle ABC$  and line perpendicular to AC passing through vertex B.

Prove that  $BA + BC > AC$

From the diagram, AM is the shortest distance from vertex A to BM. and CM is the shortest distance from vertex C to BM.

i.e.  $AM < BA$  and  $CM < BC$

By adding these inequalities, we have

$$AM + CM < BA + BC$$

$$\Rightarrow AC < BA + BC (\because AM + CM = AC)$$

$BA + BC > AC$  (Hence Proved)

Q. if one acute angle in a right angled triangle is double the other then prove that the hypotenuse is double the shortest side

Given: In  $\triangle ABC$ ,  $\angle B = 90^\circ$  and  $\angle ACB = 2\angle CAB$

Prove that  $AC = 2BC$

Construction: Produce CB to D such that  $BC = BD$  Join to AD

Proof : in triangle ABD, and ABC

$BD = BC$  ;  $AB = AB$  and  $\angle B = \angle B = 90^\circ$

By SAS congruency,  $\triangle ABD \cong \triangle ABC$

By CPCT,  $AD = AC$

$\angle DAB = \angle BAC = X^\circ$

So,  $\angle DAC = 2X^\circ \Rightarrow \angle ACB = \angle ACD$

Now in  $\triangle ADC$ ,  $\angle DAC = \angle ACD = 2X^\circ$

So,  $AD = DC$

$\Rightarrow AC = DC = 2BC$  Proved

Q. Prove that in a triangle the side opposite to the largest angle is the longest.

Solution:

Given , in  $\triangle ABC$ ,  $\angle ABC < \angle ACB$

There is a triangle ABC, with angle  $\angle ABC > \angle ACB$ .

Assume line  $AB = AC$

Then angle  $\angle ABC = \angle ACB$ , This is a contradiction

Assume line  $AB > AC$

Then angle  $\angle ABC < \angle ACB$ , This also contradiction our hypothesis

So we are left with only one possibility , $AC > AB$ , which must be true

Hence proved:  $AB < AC$

Q. Prove that in a triangle the angle opposite to the longer side is the longest.

Solution:

Given, in  $\triangle ABC$ ,  $AC > AB$ .

Construction: Take a point D on AC such that  $AB = AD$

Proof: Angle  $ADB > DCB$

$\angle ADB = \angle ABD$

So  $\angle ABD > \angle DCB$  (or  $\angle ACB$ )

$\angle ABC > \angle ABD$ , so  $\angle ABC > \angle ACB$

Q. In a  $\triangle ABC$ ,  $\angle B = 2\angle C$ . D is a point on BC such that AD bisect  $\angle BAC$  and  $AB = CD$ . Prove that  $\angle BAC = 72^\circ$

In  $\triangle ABC$ , we have

$\angle B = 2\angle C$  or,  $\angle B = 2y$ , where  $\angle C = y$

AD is the bisector of  $\angle BAC$ . So, let  $\angle BAD = \angle CAD = x$

Let BP be the bisector of  $\angle ABC$ . Join PD.

In  $\triangle BPC$ , we have

$\angle CBP = \angle BCP = y \Rightarrow BP = PC \dots (1)$

Now, in  $\triangle ABP$  and  $\triangle DCP$ , we have

$\angle ABP = \angle DCP = y$

$AB = DC$  [Given]

and,  $BP = PC$  [Using (1)]

So, by SAS congruence criterion, we have

$\triangle ABP \cong \triangle DCP$

$\angle BAP = \angle CPD$  and  $AP = DP$

$\angle CDP = 2x$  then  $\angle ADP = \angle DAP = x$  [ $\angle A = 2x$ ]

In  $\triangle ABD$ , we have

$\angle ADC = \angle ABD + \angle BAD \Rightarrow x + 2x = 2y + x \Rightarrow x = y$

In  $\triangle ABC$ , we have

$$\angle A + \angle B + \angle C = 180^\circ$$

$$\Rightarrow 2x + 2y + y = 180^\circ$$

$$\Rightarrow 5x = 180^\circ$$

$$\Rightarrow x = 36^\circ$$

Hence,  $\angle BAC = 2x = 72^\circ$

**You may also use this way:**

Let in  $\triangle ABC$ ,  $\angle C = x$

$$\therefore \angle B = 2x$$

$$\therefore \angle BAC = 180 - 3x \quad \dots(i)$$

$$\therefore \frac{1}{2} \angle BAC = \frac{180 - 3x}{2}$$

$$\therefore \angle CAD = \frac{180 - 3x}{2} \quad [ \because AD \text{ bisects } \angle BAC ]$$

In  $\triangle ADC$ ,

$$AD = DC$$

$$\Rightarrow \angle ACD = \angle CAD$$

$$\therefore x = \frac{180 - 3x}{2}$$

$$\therefore 2x = 180 - 3x$$

$$\therefore 5x = 180$$

$$\Rightarrow x = 36$$

Substituting the value of  $x$  in (i), we get

$$\angle BAC = 180 - 3x$$

$$= 180 - 3 \times 36$$

$$= 180 - 108$$

$$\Rightarrow \angle BAC = 72^\circ$$

Hence proved
